LOSS OF AIRWAY GUIDELINES

Tracheostomy tube accidentally comes out of trachea

New tracheostomies (less than seven days since tracheostomy performed)
- Patient becomes acutely hypoxic, increased pressure to ventilate, unable to detect or movement
- CALL CODE: if in ICU, follow communication plan as outlined in "unplanned removal or loss of artificial airway communication"
- Call help – remind suction catheter can go down a significant distance into the esophagus suggesting that you are in the trachea and breath sounds are usually normal.
- Remove air from balloon
- Remove inner canula, then suction
- Remove tracheostomy tube sutures – those tying tracheostomy tube to skin
- Remove tracheostomy tube
- Hyperextend the patient's neck (unless cervical spine not clear)
- Administer oxygen to tracheostomy site
- Begin face mask ventilation using a manual resuscitation bag (除外: total laryngectomy)
- Perform endotracheal tube intubation
- Begin securing equipment
  - Crash cart
  - Tracheostomy tube tray
  - Tracheostomy and endotracheal tube
  - Lights
- Replace tracheostomy tube after help and equipment have arrived (this may be in the operating room)
- May need to place endotracheal tube into tracheostomy temporarily

Mature tracheostomies – may be able to replace. If any trouble, see below.

Technique
- Preoxygenate with 100% for several minutes
- Extend the neck if the Cervical Spine is cleared
- Prepare new tracheostomy tube
  - Check balloon
  - Milk balloon back and remove all air
  - Ensure obturator is in tracheostomy tube
  - Lubricate balloon with jelly
- Suction old tracheostomy tube with suction catheter
- Remove skin sutures that held old tracheostomy tube if still present
- Make sure labeled retention sutures are not crossed – the retention sutures are used to open tracheostomy incision in case tracheostomy tube has slipped out – do not pull hard on the sutures.
- Place new tracheostomy tube through stoma and infuse balloon
- Remove obturator and place inner cannula
- Confirm breath sounds and oxygen saturation
- Secure in neutral position

Difficult tracheostomy tube change: If tracheostomy tube does NOT go in easily/well - STOP
1. Reassess
2. Do NOT forcefully or blindly insert tracheostomy tube into stoma
3. Appropriate steps include:
   a. Call for help
   b. Deliver oxygen to tracheostomy opening
   c. Consider endotracheal intubation orally
   d. Consider passing endotracheal tube exchange catheter if tracheostomy incision opening can be visualized
Consider establishing airway using use of bronchoscope

Elective tracheostomy tube change, downsizing, and maintenance

Criteria to downsize tracheostomy tube
- Mental status appropriate to protect airway
- Secretions less than every two hours
- No active pneumonia
- No aspiration of feedings
- Consider downsizing from 8 to 6 as soon as clinically appropriate
- Consider using uncuffed tube when clinically indicated

Seven days post placement
- Cut sutures
- Clean and change inner cannula
- Replace trach access device
- Should not change tracheostomy tube before seven days unless emergency e.g., plugged, broken balloon, tube has slipped out, etc.

First tracheostomy tube change ** if problems of difficult airway expected consider location for trach change be ICU or OR
1. First change should be performed by 14 days post placement
2. There should be two persons present at the tracheostomy tube change, one of whom must be a MD
3. Who should do the first tracheostomy tube change
   - Faculty or Senior Residents' fellow with Faculty readily available
   - Senior residents' fellow should have performed tracheostomy change with faculty before doing change by himself or teaching senior resident

Personnel and equipment
- Respiratory therapist and nurse (RN or LPN) by bedside
- Tracheostomy tray near bedside (or nearby)
- Rapid Sequence Intubation tray at bedside
- Replacememt trachestomy tube
- Smaller size tracheostomy tube by bedside e.g., if tracheostomy tube size is 8.0 than have size 6.0 by bedside
- Endotracheal tube, suture, and intubation equipment by bedside – crash cart by door if on the floor
- suction cart in the ICU
- Tracheostomy tube obturator by bedside
- New Velcro tracheostomy tube tie by bedside
- Resuscitation bag by bedside
- Make sure there is adequate lighting
- Suction and suction catheter
- Scissors at bedside to remove skin sutures
- Oxygen source and continuous pulse oximetry

Technique
- Preoxygenate with 100% for several minutes
- Extend the neck if the Cervical Spine is cleared
- Prepare new tracheostomy tube
  - Check balloon
  - Milk balloon back and remove all air
  - Ensure obturator is in tracheostomy tube
  - Lubricate balloon with jelly
- Suction old tracheostomy tube with suction catheter
- Remove skin sutures that held old tracheostomy tube if still present
- Make sure labeled retention sutures are not crossed – the retention sutures are used to open tracheostomy incision in case tracheostomy tube has slipped out – do not pull hard on the sutures
- Place new tracheostomy tube through stoma and infuse balloon
- Remove obturator and place inner cannula
- Confirm breath sounds and oxygen saturation
- Secure in neutral position

Difficult tracheostomy tube change: If tracheostomy tube does NOT go in easily/well - STOP
1. Reassess
2. Do NOT forcefully or blindly insert tracheostomy tube into stoma
3. Appropriate steps include:
   a. Call for help
   b. Deliver oxygen to tracheostomy opening
   c. Consider endotracheal intubation orally
   d. Consider passing endotracheal tube exchange catheter if tracheostomy incision opening can be visualized
Consider establishing airway using use of bronchoscope
